1. **kNN**

(a) The training rate **increases** as 'k' increases from 1.

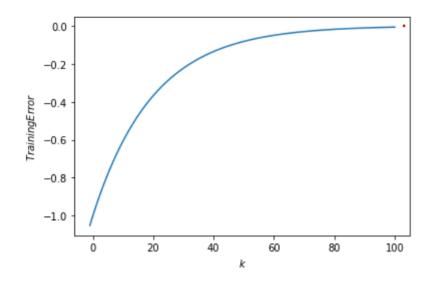

Figure 1: Training Error vs. k.

- (b) The generalisation error for k =1 is maximum because overfitting of the model has occured. As k increases the generalisation error reaches a minima after which generalisation error increases as k increases
- (c) The Curse of Dimensionality primarily occurs in Machine learning alforithms that are distance metric dependent some way or the other which includes k-NN

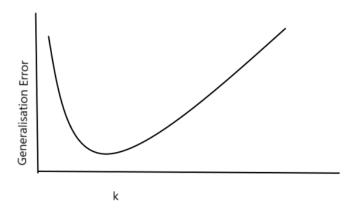

Figure 2: Generalization Error vs. k.

algorithm as well.

Two reasons supporting the above statements are as follows:

i. k-NN uses count of the closest neighbours in a given space for which it may makes use of the Euclidean distance metric among other distance metrics. Now as the number of diumensions increase the **distance metric goes on to become meaningless**.

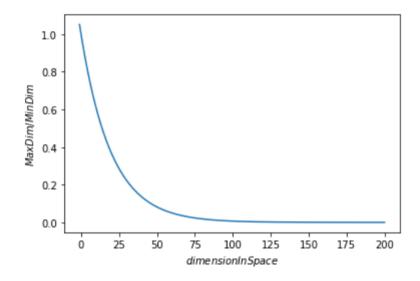

Figure 3: Max Dim/Min Dim vs. Dimensions in Space

ii. Density prer region in a given hypersurface decreases i.e we find fewer observations per region.

For example, consider a sphere inscribed within a cube assuming data points on this as dimensions increase shows that

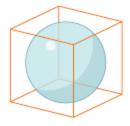

Figure 4: Cube-Sphere are regions having datapoints

 $\frac{Volume of sphere}{Volume of cube} \approx 0$

Hece density reduces!

- (d) The decision boundary diagram for a 1-NN is a Voronoi Diagram.
 - i. A decision boundary is defined to be at equal distance from the two points in question (belonging to different classes)
 - ii. Hence any point within the decision boundary is considered to be belonging to that class

Figure 5: A voromoi Diagram in

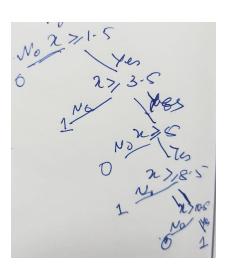

Figure 6: A Decision Tree Diagram

The decision taken on the basis of Decision Tree will alo be the same:

Hence comparing we get same results!

2. Bayes Classifier

Grun:
$$O_{i_1}^2 = 0.0092$$
, $N_2 = 10$ $9 = 0.6$
 $O_{i_2}^2 = 0.0092$, $N_2 = 4$
 $O_{i_3}^2 = 0.0092$, $O_{i_4}^2 = 0.0092$
 $O_{i_4}^2 = 0.0092$, $O_{i_4}^2 = 0.00092$
 $O_{i_4}^2 = 0.0092$
 $O_{i_4}^2 = 0.00092$
 $O_{i_4}^2 = 0.00092$

- (a)
- (b) Asuming independence of attributes as in the Naive Bayes assumptio we can solve the prolem as follows":

$$\Pr(Politics \mid testCase) = \frac{\Pr(Politics \mid testCase) \Pr(Politics)}{\Pr(test_{c}ase)}$$

The Right hand side can be computed as below:

 $=\frac{\Pr(1|Politics)\Pr(0|Politics)\Pr(0|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(0|Politics)\Pr(0|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)\Pr(1|Politics)$

$$= \frac{\frac{2}{6} * \frac{5}{6} * \frac{5}{6} * \frac{5}{6} * \frac{5}{6} * \frac{1}{6} * \frac{4}{6} * \frac{1}{6} * \frac{6}{12}}{0.5^8}$$

= 0..38

3. Decision Trees

- (a) Accuracy = 0.8119
- (b) Accuracy = 0.8281
- (c) i. Accuracy with Gini Index on an unpruned tree = 0.8119
 - ii. Accuracy with Entropy on a pruned tree = 0.8265 There has been an improvement in the accuracy because of the following reasons:
 - A. The only advantage of Gini index is that it is computationally faster, there is not much effect on accuracy as we see.
 - B. Pruning reduces the complexity of the tree in higher dimensions thus reducing overfitting and hence a better result on test data
